

ALGORITHMS

DATA STRUCTURES

Extrational process \Rightarrow FID numbers

Relationships between objects

Lecture 1 SORTING

Problem definition:

- Input: Sequence of elements x_1, x_2, \dots, x_n
- Ordering relation (\leq) on elements
- Output: Sorted sequence of n elements according to given order.

Eg: [15, 3, 27, 49, 23, 18, 6, 10, 31] ref
[1, 3, 6, 15, 18, 23, 27, 31, 49]

Algorithm

Selection Sort()

- 1) Find smallest element \rightarrow swap to 1st position
- 2) Find next smallest \rightarrow swap to 2nd position
- 3) Iterate till array is sorted. $A = [1]A$

```

def SelectionSort (array):
    n = length of array
    for i in range (0, n):
        minIndex = i
        for j in range (i+1, n):
            if array [j] < array [minIndex]:
                minIndex = j
        // Swap elements to i
        array [i], array [minIndex] = array [minIndex], array [i]
    return array

```

Write a python program and run doctests

Pseudo code

SelectionSort [A]:

```

1> for i=0 to n-1 do
2>     // find min in A[i..n-1]
3>     minIdx = i
4>     for j=i+1 to n-1 do
5>         if A[j] < A[minIdx] then
6>             minIdx = j
7>     // Swap A[i] with min of A[i..n-1]
8>     tmp = A[i]
9>     A[i] = A[minIdx]
10>    A[minIdx] = tmp

```

Analysis of an Algorithm

- (1) Show that an algorithm is correct
→ Algorithm computes correct output for every possible input
- Algorithm terminates (total correctness)
- (2) Analyse the running time and other properties
→ Efficiency of the algorithm is a ref.
→ Performance and Speed
= [Complexity of algorithm] × [Input size]

Correctness of Selection Sort Algorithm

Properties after iteration (ii) (") thing

- * Array contains same values as in beginning
- * $A[0 \dots i]$ is sorted correctly.
- * values in $A[0 \dots i] \leq$ values in $A[i+1, \dots n-1]$

Proof by induction

disjoint

- Induction basis ($i = 0$) : [check above props]
- Induction step ($i > 0$) :

To check how fast the algorithm runs

Time taken to sort next entry - total

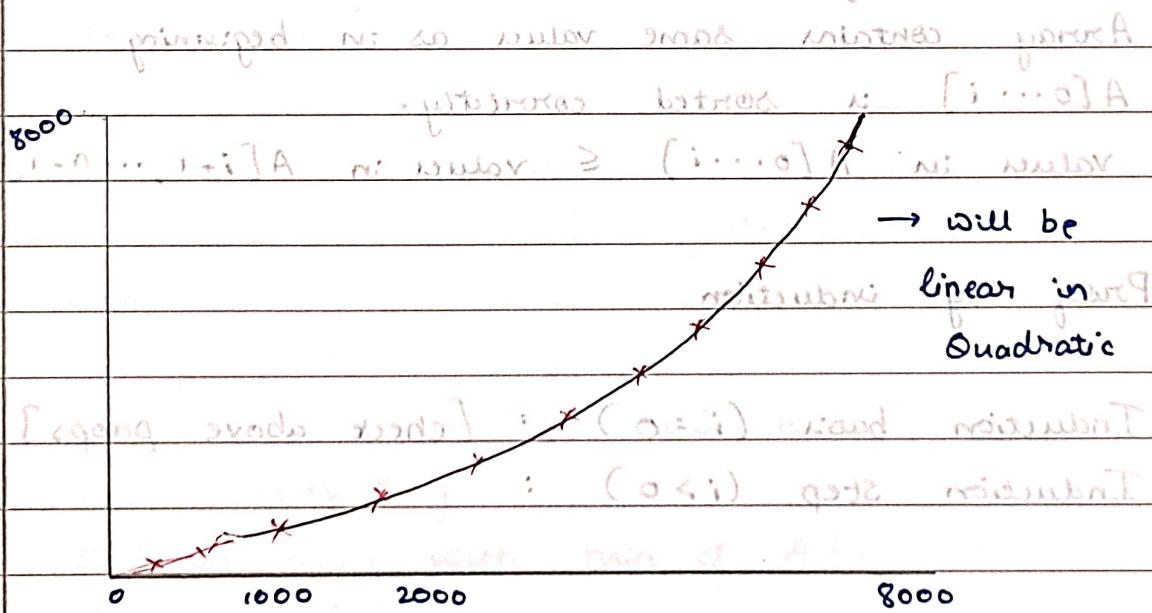

a) Measuring Time : ~~math~~ (python) an for selection

```

import time milliseconds microseconds as time
start_time = time.time() milliseconds microseconds as start_time
// Algorithm large values here
run_time = (time.time() - start_time) * 1000

def selection_sort_performance():
    for n in range(100, 8001, 100):
        array = [random.randint(0, 2*n) for
                 k in range(0, n)]
        start_time = time.time()
        selection_sort(array)
        run_time = (time.time() - start_time) + 1000
        print ("%d\t%.1f" % (n, run_time))

```

gnuplot: set terminal postscript
plot data.txt

Observation

- Became slower over-proportionally when size of array increases : (A) ~~real experiment~~
- Time grew roughly quadratically with size of the array. ~~where is linear~~
- Array $2 \times$ size $\Leftrightarrow 4 \times$ time to sort arr
- Array $3 \times$ size $\Leftrightarrow 9 \times$ time to sort arr
- Running time $(\text{f}(n))$ of selection sort algorithm is indeed quadratic. $L = n^2 = n^2$

Implementation of the Algorithm

Algorithm

Insertion Sort

- Beginning (prefix) of array is sorted
 - ↳ one element per iteration
- Step by step each element will be sorted.

4	15	3	27	49	23	18	6	1	31
---	----	---	----	----	----	----	---	---	----

- 1) Start with 15, then 3 as $3 < 15$ swap them
- 2) Move to 27, 0 to $i+1$ is sorted
- 3) Move to 49, 0 to $i+1$ is sorted
- 4) Move to 23, $23 < 27 < 49$ Swap twice — 2 with 27
- 5) Continue in some way

Pseudo code

~~at the end (0, i) will be
numbers already sorted.~~

Insertion Sort (A) :

```

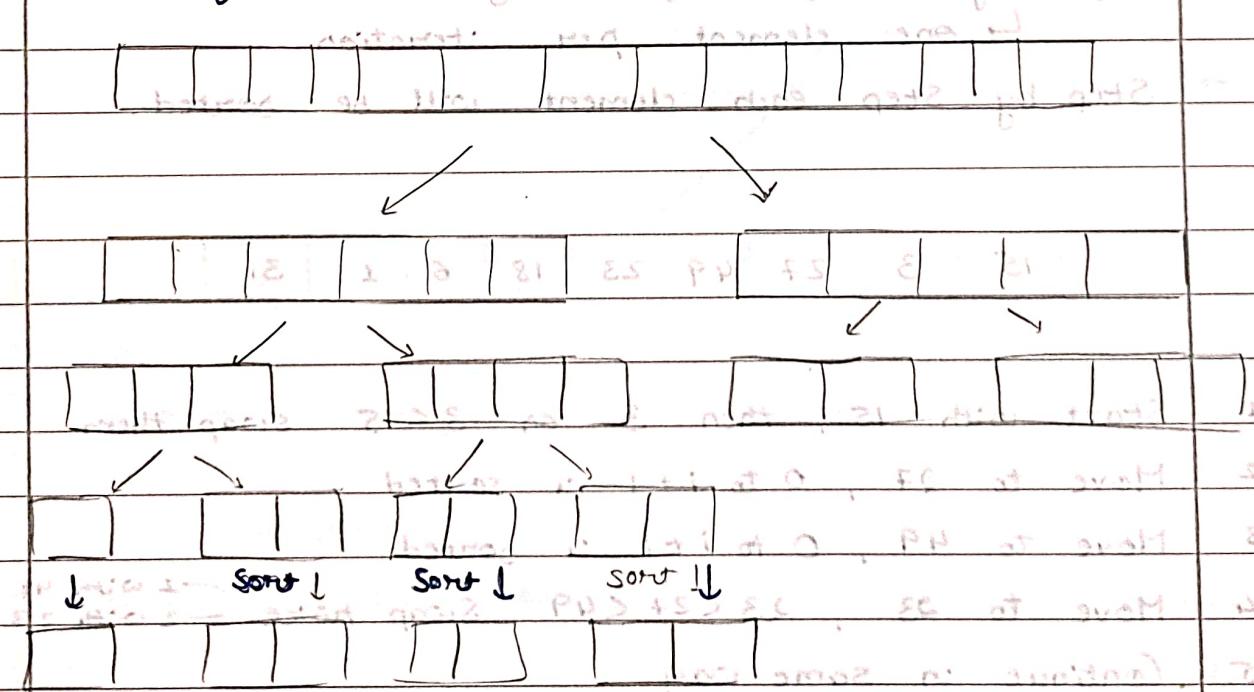

1 for i = 0 to n - 2 do
2   // prefix A[0...i] is already sorted
3   pos = i + 1
4   while (pos > 0) and (A[pos] < A[pos - 1]) do
5     swap (A[pos], A[pos - 1])
6   pos = pos - 1
    
```

Algorithm

Quick Sort (Divide & Sort)

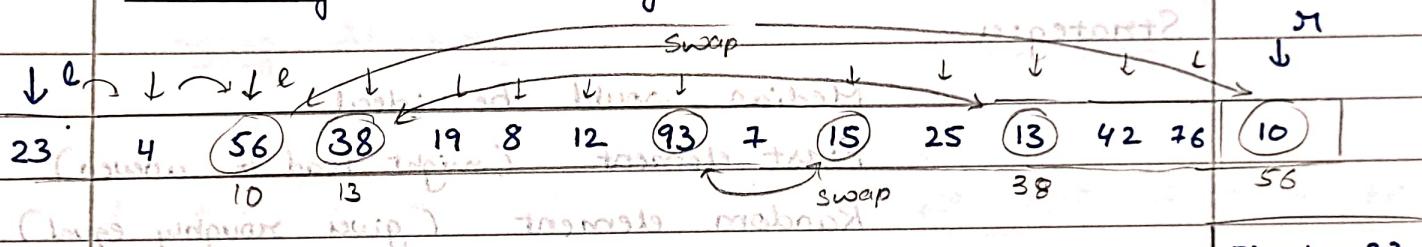

→ Divide array into two parts

* left part small elements - right large

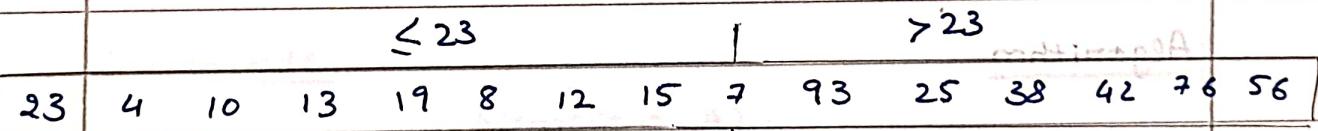

- 1> Divide the array into left and right part
 (first or middle element) left \geq 1 \leq A elements right \geq 1 \leq A elements
 P partitions \rightarrow partition, $P(A) \rightarrow (A_1, A_2)$
- 2>
 - (a) Sort elements in left recursively
 - (b) Sort elements in right recursively
- 3> As soon as the sub problems become small enough such that sorting becomes trivial recursion ends and sorted array left with element p in middle continuing with right array remains step by step

Partitioning the Array

1. Increment l as long as $A[l] \leq$ pivot
2. Decrement r as long as $A[r] >$ pivot
3. Swap when both are struck

Procedure

- Two variables l, r to iterate over the array from left and the right

- Increment left until $A[l] > x$ (element goes to right)
- Decrement right until $A[r] \leq x$ (element goes to left)
- Swap $A[e] \leftrightarrow A[r]$, increment left, decrement right
- Divide partition as soon as left and right meet

Choice of Pivot

Random number. This determines how large the two parts become when array is divided. The algorithm works best if size of two parts are almost equal.

Strategies

→ Median would be ideal

→ First element (might lead to uneven)

→ Random element (gives roughly equal)

→ Median of ≥ 3 random elements.

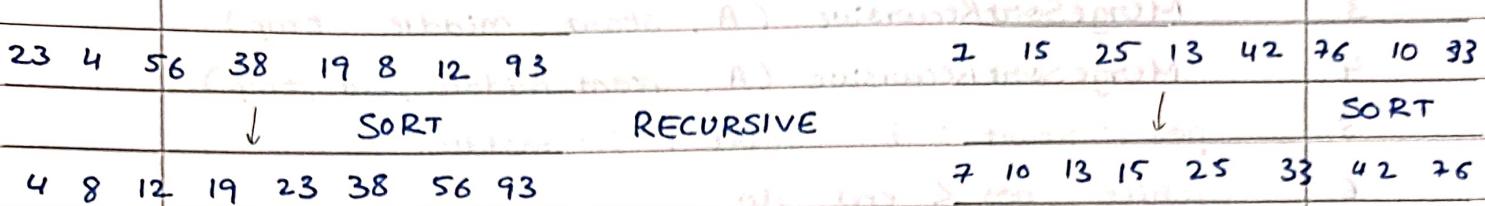

Algorithm

MergeSort

MergeSort is also based on divide & conquer.

23 4 56 38 19 8 12 93 7 15 25 13 42 76 10 33

~~L1 (Divide + Recur) + merge = 2 times~~

4 7 8 10 12 13 15 19 23 25 33 38 42 56 26 93

- * Divide trivial for Mergesort
- * Merge requires more work

Merging Algorithm

i ↗	i ↗	SORTED	↓	↓	j ↗	j ↗	SORTED
4	8	12 19	23 38 56 93		7	10 13 15	25 33 42 76

4 < 7 7 < 8 8 < 10 10 < 12 ...

4 | 7 | 8 | 10 | ... : merging algorithm

then algorithm ends : merging algorithm

Pseudo Code

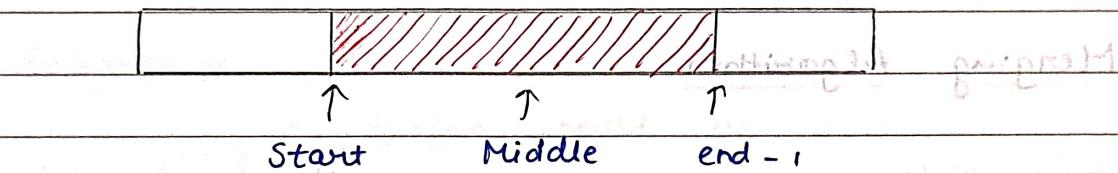

Mergesort(A) :

1. allocate array tmp to store intermediate results
2. MergesortRecursive(A, 0, n, tmp)

MergesortRecursive(A, start, end, tmp)

1. if end - start > 1 then

2) $\text{middle} = \text{start} + (\text{end} - \text{start}) / 2$.
 3) `MergeSortRecursive(A, start, middle, tmp)`
 4) `MergeSortRecursive(A, start, middle, end, tmp)`
 5) $\text{pos} = \text{start}; i = \text{start}; j = \text{middle}$
 6) `while pos < end do`
 7) `if i < \text{middle} \text{ and } (j \geq \text{right} \text{ or } A[i] \leq A[j]) \text{ then}`
 8) `tmp[pos] = A[i]; pos++; i++`
 9) `else`
 10) `tmp[pos] = A[j]; pos++; j++`
 11) `for i = start to end - 1 do A[i] = tmp[i]`

Summary:

- * Simple Sorting Algorithm : Selection & Insertion Sort
- * Recursive Sorting Algorithm : Quick & Merge Sort
